Dis 14: TA Review Session

1 List of Concepts (Not Exhaustive)

- **Descriptive statistics**: set of methods used to summarize or present your data
  - How to calculate population parameters, given population data (mean, standard deviation, variance, covariance, correlation)
  - How to calculate the corresponding sample statistics, given sample data (keep in mind of potential degree of freedom adjustment)
  - How good are our descriptive statistics from the sample?
    - Evaluate whether a sample estimator is unbiased, relatively efficient, or consistent
- **Inferential statistics**: set of methods used to draw conclusion or make inference about the population using a sample data
  - Tools needed to make inference:
    - Probability (joint probability, conditional probability, Bayes law, etc.)
    - Random variable (assigns numbers to the outcomes of an experiment)
      - Discrete random variable, and the distributions they can follow (Binomial, Poisson)
      - Continuous random variable, and the distributions they can follow (Uniform, Normal, Exponential, Student-t, Chi-squared, F)
    - Sampling distribution: distribution of the sample statistic ($\bar{X}$, $\hat{p}$, $\bar{X}_1 - \bar{X}_2$)
  - How are inferences made:
    - Hypothesis testing – 3 different ways to testing whether the null hypothesis is rejected:
      1. Test statistic & rejection region (for one-tailed or two-tailed test): reject if test statistic is in the rejection region constructed using significance level α
      2. p-value (for one-tailed or two-tailed test): reject if p-value is less than α
      3. Confidence interval (for two-tailed test only): reject if the hypothesized value in null is outside of the confidence interval with $1 - \alpha$ confidence level
  - What population parameter(s) can we make inference on?
    - From one population:
      - μ_X, given that σ_X is known
      - μ_X, given that σ_X is unknown
      - σ_X^2
      - p (proportion of success from a Binomial experiment)
    - From two populations:
      - $\mu_1 - \mu_2$
      - $\frac{\sigma_1^2}{\sigma_2^2}$
      - $p_1 - p_2$
    - About relationships: simple linear regression
      - β_1: if β_1 is concluded to be non-zero, then the slope coefficient is statistically significant, meaning that the dependent and the independent variable share a nonzero relationship

2 Exercises

1. One of the food carts outside of Memorial Union sells spring rolls, and you want to study how many spring rolls this food cart sells in any given hour. Suppose that the amount of spring rolls sold in any hour is independent from other times, and you know that the true standard deviation of the number of spring rolls sold in an hour equals to 2.

   (a) Let X be a random variable denoting the number of spring rolls sold in an hour from this food cart. What distribution does X follow?

   (b) What's the probability that the number of spring rolls sold in an hour would be less than 4?

2. App developers often perform A/B testing to see whether a change is well perceived. Suppose that 100 people are randomly selected to participate in an A/B testing. In this test, the developer randomly assigns all 100 users to one of the two equally-sized groups: the control group, and the experiment group. Users in the control group sees no change in app interface, while users in the experiment group is presented with a pop-up window that encourages them to change their current status.

   The app developer observes that, on average, the experiment group changes their status 5 more times compared with the control group. The estimated standard error of the mean is 9 for the control group, and 4 for the experiment group. The population standard deviations are unknown, and they are not assumed to be equal.

   (a) What's the sample variance of the amount of times users change their status for users in the experiment group?

   (b) Test whether the new pop-up window makes people change their status more on average, using a 5% significance level.

3. You're interested in learning the average amount of daily coffee consumption among Econ students taking stats and econometrics classes. There are in total 1400 students enrolled in these classes, and you collected a random sample of size 100.

   Suppose that the true average amount of coffee consumed by such Econ students is 11 oz per day, and the population variance of such Econ student's coffee consumption is known, and it is 4 oz per day.

   (a) Let X be the amount of coffee consumed daily by Econ students enrolled in stats and econometrics classes. What distribution does the sample average $\bar{X}$ follow?

   (b) What's the probability that the average found in your sample ends up being greater than 10.7 oz per day?

Probability table for a Poisson distribution

TABLE 2 Poisson Probabilities

Tabulated values are $P(X \le k) = \sum_{x=0}^{k} p(xi)$. (Values are rounded to four decimal places.)
